DATA MODEL · BASELINE V2 · DRAFT

Data model, entities and relationships

* marks target-design items that the running demo implements in a thinner form (see notes)

NOTES

* Demo store is intentionally thin: metadata lives in YAML files with exactly this structure; transactions and telemetry live in SQLite.

* Target store: relational (Azure SQL) for metadata and transactions, time series for telemetry, optional graph store for event lineage.

* Every transaction row keeps the eventId that created it, so any item can be traced back through causationId and parentEventId to its root.

* Hard reset keeps every metadata entity and purges every transaction entity, then seeds nominal telemetry. Soft reset keeps all rows.

FK = reference to another entity. Capability types are all modeled; only Manufacturing is simulated in the demo.
